Gradient descent

Have some function $J(\theta_0, \theta_1)$ Or $J(\theta_0, \theta_2, \theta_2, \ldots\ldots\ldots\ldots, \theta_n)$

Want $\min\limits_{\theta_0, \theta_1} J(\theta_0, \theta_1)$

Outline:

- Start with some θ_0, θ_1 e.g. $\theta_0 = 0$, $\theta_1 = 0$
- Keep changing θ_0, θ_1 to reduce $J(\theta_0, \theta_1)$

  until we hopefully end up at a minimum

$$\theta_0 := \text{temp0}$$
$$\text{temp1} := \theta_1 - \alpha \frac{\partial}{\partial \theta_1} J(\theta_0, \theta_1)$$

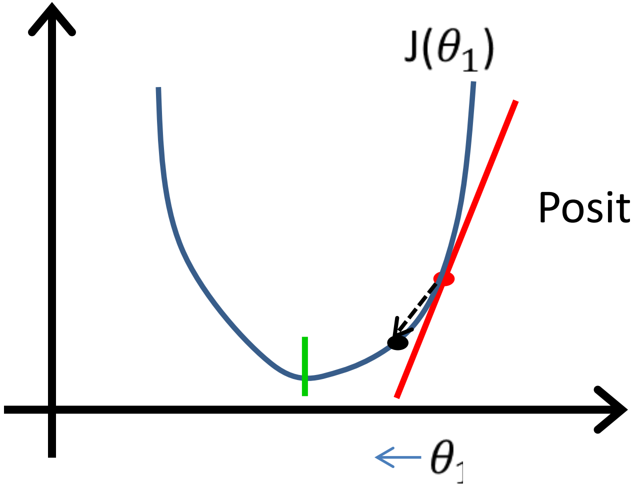
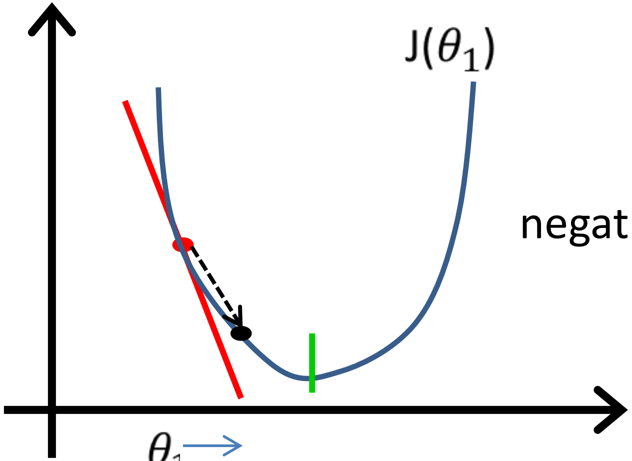
}



Positive slope

$$\frac{\partial}{\partial\theta_1}J(\theta_1)>0$$

$$\theta_1 := \theta_1 - \alpha\frac{\partial}{\partial\theta_1}J(\theta_1)$$



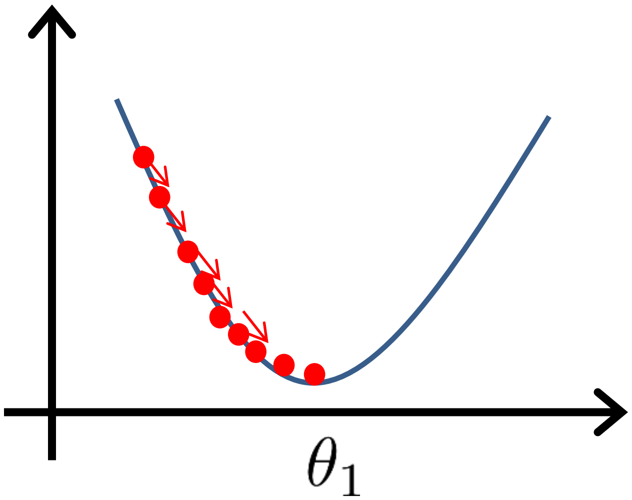
negative slope

$$\frac{\partial}{\partial\theta_1}J(\theta_1)<=0$$

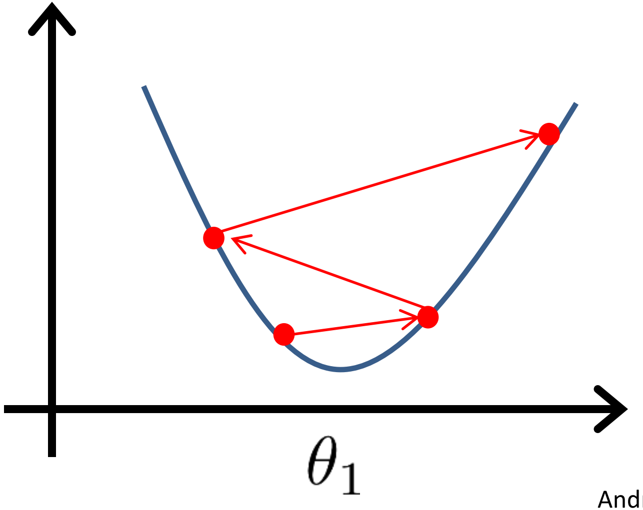
$$\theta_1 := \theta_1 - \alpha\frac{\partial}{\partial\theta_1}J(\theta_1)$$

$$\theta_1 := \theta_1 - \alpha \frac{\partial}{\partial \theta_1} J(\theta_1)$$

If α is too small, gradient descent can be slow.



If α is too large, gradient descent can overshoot the minimum. It may fail to converge, or even diverge.



Gradient descent can converge to a local minimum, even with the learning rate α fixed.

$$\theta_1 := \theta_1 - \alpha \frac{d}{d\theta_1} J(\theta_1)$$

As we approach a local minimum, gradient descent will automatically take smaller steps. So, no need to decrease α over time.
